

Student Registration Management System:

A college wants to develop a web-based Student Registration Management System to collect and maintain student information digitally. The application should provide a registration form where students can enter their personal and academic details such as name, age, email, password, gender, selected course, multiple skills, and address. When the student submits the form, the data should be sent to a Servlet using an HTTP GET request. The Servlet must read all submitted form parameters, validate and process the received information, and use JDBC with a MySQL database to store the student details securely and efficiently. The system should also provide options to search for a student using their student ID, view all registered students, and delete a student record when required. Students are expected to demonstrate their understanding of HTML forms, GET requests, request parameters, Servlets, JDBC, PreparedStatement, SQL queries, and database connectivity while developing this application.

Inside webapp:

Task: ABC Bank Online Banking System

Develop a **Java Servlet-based ABC Bank Online Banking System** with the following requirements:

Scenario

ABC Bank wants to develop an online banking portal where customers can log in and access their banking information.

The application should contain:

- Customer Login
- Customer Dashboard
- Account Details
- Transaction Details
- Logout

Requirements

1. The bank has common information such as **Bank Name, Branch Name, and Customer Care Number** that may be required by different Servlets in the application.
2. The **LoginServlet** has its own configuration value called **Login Mode**, which is required only by the LoginServlet.
3. After a customer successfully logs in, the customer should be taken to the **Dashboard** without creating a new browser request.
4. The bank has a **common header** containing the bank name and customer portal title. This header should be reusable on the Dashboard, Account Details, and Transaction Details pages.
5. If a customer tries to access Account Details or Transaction Details without logging in, the customer should be sent back to the Login page.
6. When the customer clicks **Logout**, the session should be terminated and the customer should be returned to the Login page.

Student Task

Develop the application using the appropriate Servlet mechanisms for:

- Application-wide bank information
- LoginServlet-specific configuration
- Moving from Login to Dashboard
- Reusing the common header
- Returning unauthorized/logged-out customers to the Login page
